Mean Absolute Predicted Error (MAPE)

Mean Absolute Predicted Error (MAPE) values were calculated using the formula:

MAPE [%] = (100/N) $\times \Sigma$ | (P _{actual i} – P _{predicted i}) / P _{actual i} |; sum from i = 1 to i = N

where

P actual i = actual HDD or CDD on day i,

P predicted i = forecast value of HDD or CDD on day i, and

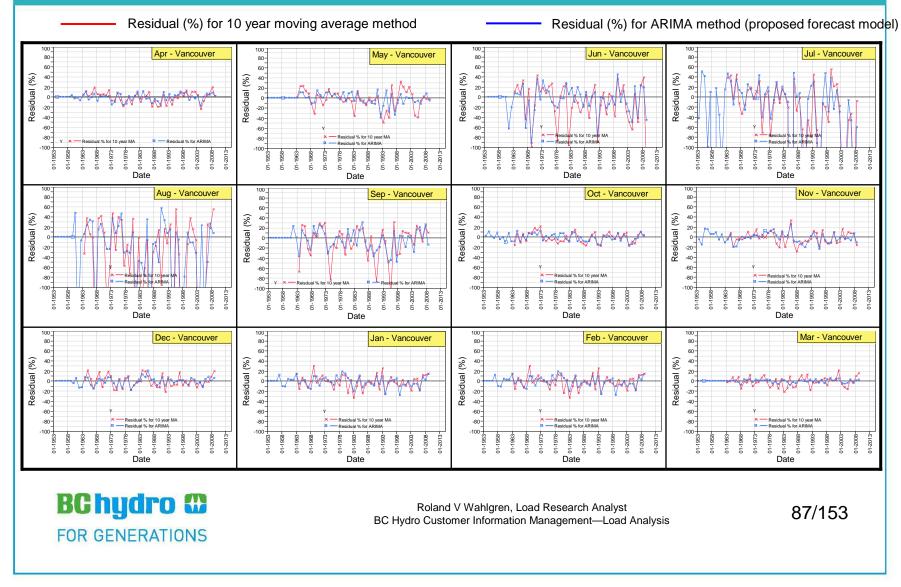

N = total number of data points.

MAPE is a useful statistic for quantifying the amounts by which predicted values differed from actual values of some variable. A MAPE of 19%, for example, would tell us, "...on average the difference between the fitted values and the actual values is 19%." (Stellwagen, 2006). MAPE is the standard for load forecasts by energy utilities (Yazdi, 2009) and is one of the statistics reported by forecasting software such as SAS JMP.

Acid Tests

Acid Tests

So far, so good—backcasts appear to have confirmed superiority of the new probabilistic model with climate inputs over the static and dynamic moving average models. MAPEs were always lowest for the new probabilistic model. But, what about stepping back in time and forecasting forward for five years? Compare (using MAPE, slide 86) the forecasts to the actual degree day values observed during these five years. Will the new model stand up to such "acid tests"?

Initial experiments with the first four acid tests gave disappointing results for the new model. These tests were based on the Vancouver Airport HDD time series from 1981–2009 used by BC Hydro's Load Forecasting division or the 1953-2009 series from Load Analysis. Monthly HDD forecasts were made for Apr 2001 to Mar 2006. The new model performed no better than either static or dynamic moving average models. Through a chance re-reading of an article about climate change in *Science*, I realized that this forecast period occurred within periods of stationarity of the time series for the Global Mean Monthly Temperature Anomalies (Kerr, 2009) and Vancouver Airport HDDs. Therefore, it was not surprising that the moving average forecasts performed nicely. The relatively short (30 year) duration of the 1981–2001 observations further handicapped functioning of the new model which depended on incorporating into its algorithms cycles revealed over longer time periods.

Disappointment was tempered further when it was discovered researchers working on short-term weather forecasting models for model predictive control of commercial buildings, which would not usually be experiencing noticeable trends, found that, "the results show that even the most complicated nonlinear autoregressive neural network with exogenous input does not appear to warrant the additional efforts in forecasting model development and training in comparison to the simpler MA [moving average] models" (Florita and Henze, 2009, p. 835).

To ensure a fair comparison between forecasting methods, Acid Test No. 5 was done using the 1953–2009 time series used for all the other analyses in this project. These acid tests began **forecasts in Apr 1993** (within a **period of non-stationarity** with a decreasing HDD trend). **Now the probability model out-performed the moving average models** for the crucial heating months of Sep through Feb. Accuracy in Mar and Apr was acceptable, although not quite as good as the moving average models. Experimentation showed that the probabilistic model was sensitive to the correct application of climate inputs. If the bivariate analyses done earlier had significant correlations between HDD and a certain climate index, MAPE decreased when all appropriate inputs were applied. If a significant climate index input was omitted, MAPE increased. Finally, Acid Test No. 6 checked thoroughly whether using as ARIMA model inputs climate indices such as SOI, PDO, NPI, or ALPI would improve forecasting accuracy.

Roland V Wahlgren, Load Research Analyst BC Hydro Customer Information Management—Load Analysis

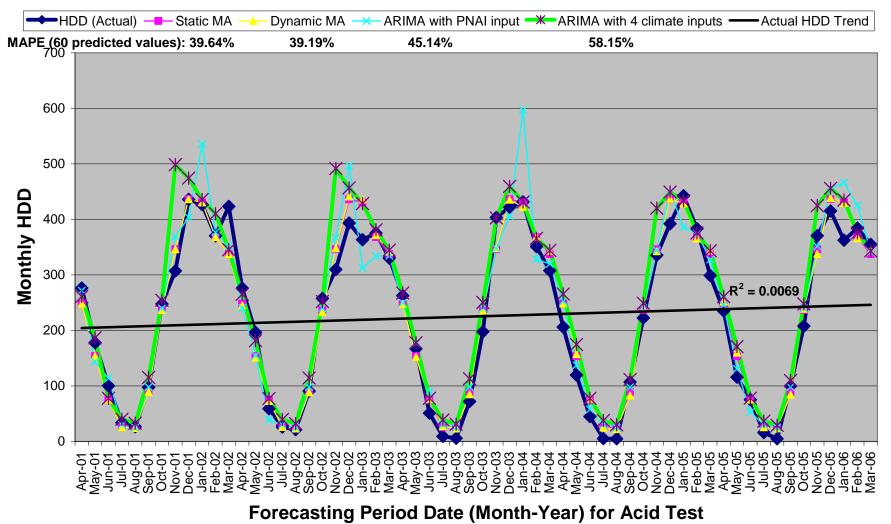

Guide to the Acid Tests

Variability in forecast accuracy during forecast period

Acid Test No. 5 MAPE against forecast period

Forecasting Period Date (Month-Year) for Acid Test

Exploration of climate influences on HDD for Vancouver (1 of 3)

Hypothesis: Best fitting indices (coloured cells) were likely to be the best inputs for maximizing climate input information to ARIMA model for increased forecasting accuracy.

The data collected for the strength of fit table below used bivariate analyses similar to the monthly analyses for HDD against PNAI illustrated on Slide 28. Strength of fit was quantified by the value giving the Analysis of Variance (ANOVA) probability that the F-statistic is greater than the critical statistic. Lower probabilities indicate better fits. Table is charted in Slides 110 and 111.

Strength of fit between HDD Vancouver and climate indices by month

BChydro

Roland V Wahlgren, Load Research Analyst BC Hydro Customer Information Management—Load Analysis

Exploration of climate influences on HDD for Vancouver (2 of 3)

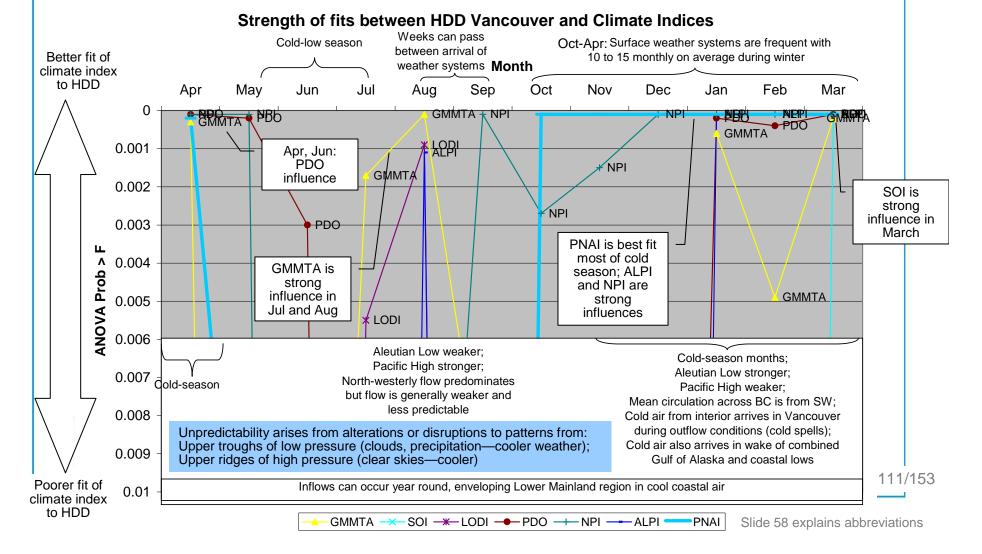

Here is an overview of the strength of fits. This is far "too busy" to comprehend easily, so zoom in, next slide, filtering out all probabilities greater than 0.01. The y-axis was reversed in these charts, so that better fits would be grouped near the top of the chart.

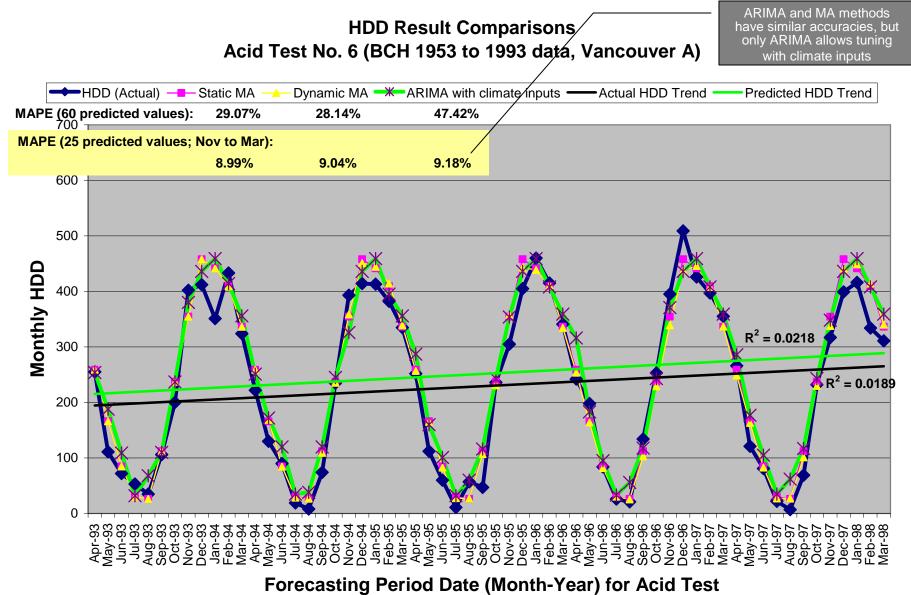

Strength of fits between HDD Vancouver and Climate Indices

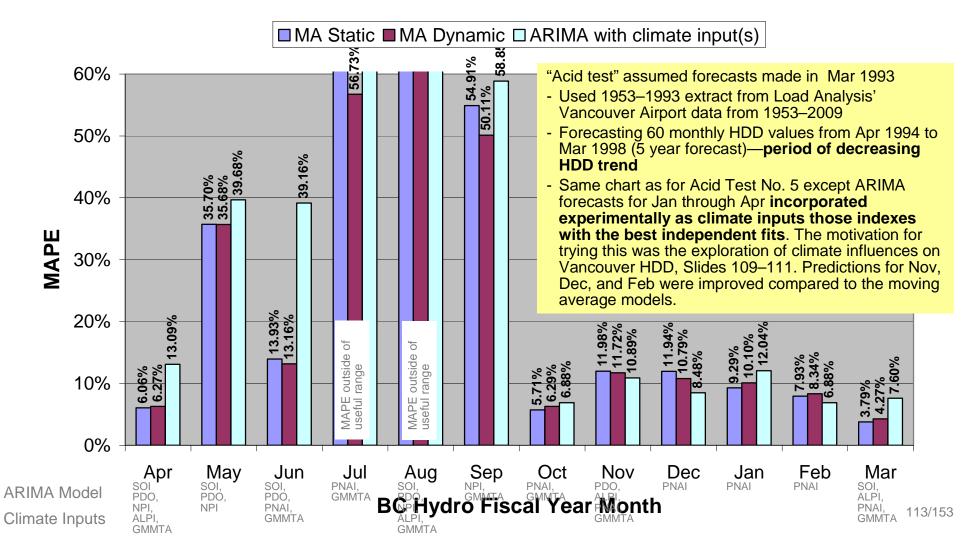

Exploration of climate influences on HDD for Vancouver (3 of 3)

This view focused on indices with "good fits" to Vancouver HDD. Climate notes (Klock and Mullock, 2001, ch. 3) highlight: (1) differences between cold and warm seasons, (2) events which increase heating needs, and (3) difficulty of making reliable predictions.

MAPE for HDD forecasting methods BCH 1953 to 1993 data (Vancouver A)

Knowledge

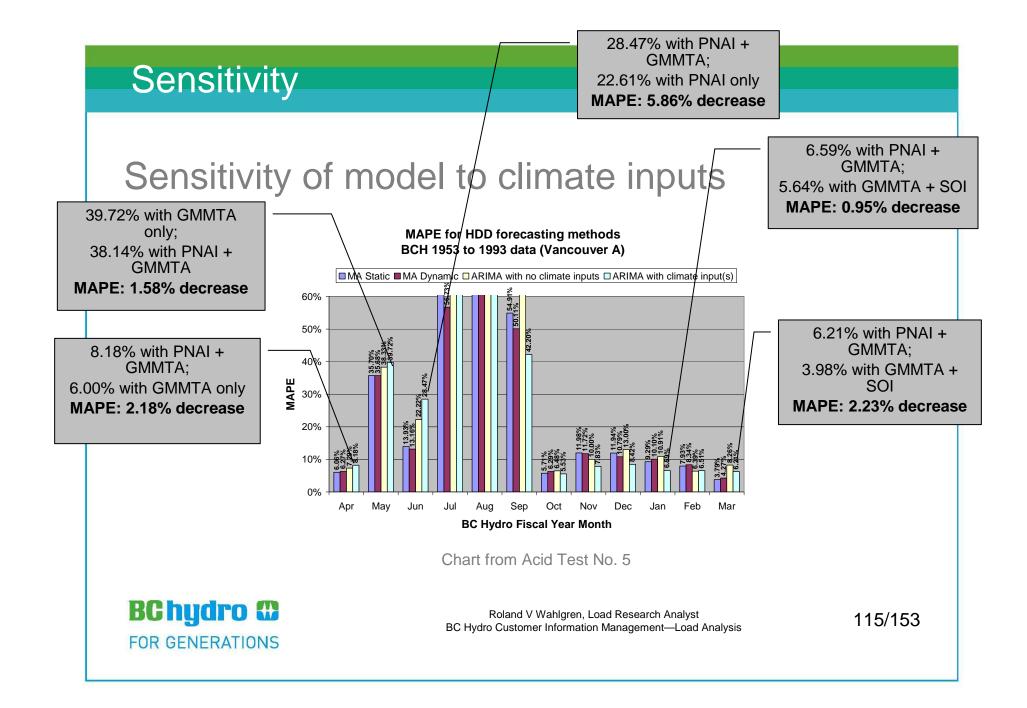

Knowledge gained from "Acid Tests"

- Backcasting alone is not a sufficient test of forecasting accuracy
- Best test of forecast accuracy is an "Acid Test", meaning to step back in time, make forecasts, and compare forecast values from alternative methods to actual values using Mean Absolute Predicted Error (MAPE)
- Acid tests should select historical data representing periods of stationarity and non-stationarity for separate tests
- Backcasting period covered periods of stationarity **and** non-stationarity; Therefore, this performance test for forecasting accuracy favoured the probabilistic model with climate inputs over the empirical moving average techniques
- Acid test technique is useful for testing various combinations of climate inputs and even new previously unused inputs (such as Southern Oscillation Index) to see if MAPE can be minimized. Better understanding develops of monthly regional climate influences. This experience can later be used in producing new forecasts
- Avoid forecasting HDD for Jul and Aug, Both moving average models as well as ARIMA model yield such high MAPEs that the predicted values are practically useless
- Avoid using unnecessary, extra inputs because over-fitting is likely (NIST/SEMATECH, 2009). Best results

were obtained when using one or two climate inputs at a time, not all four at once. – Over-fitting (e.g., using all inputs all the time) increases likelihood that noise will be interpreted as the actual signal

More questions

More questions than answers?

- Why did 1999 through 2008 Global Mean Monthly Temperature Anomaly time series from NASA GISS reveal a significant trend while the Met Office Hadley Centre's HadCRUT3 temperature record showed no trend?
- Why did bivariate analyses by month show no significant fits between (Vancouver, Victoria, and Prince George) HDDs and the Pacific North American Index during Aug and Sep when the NASA Goddard Space Flight Center Global Change Master Directory claimed that the PNA pattern is weakest in Jun/Jul?
- What is explanation for cycles, apparently unrelated to global climate processes, observed in spectra of the continental-scale climate indices?
- Why did adding SOI as a climate input decrease MAPE in Jan for Acid Test No. 6 even though bivariate analysis showed no significant correlation between HDD and SOI in Jan?

Roland V Wahlgren, Load Research Analyst BC Hydro Customer Information Management—Load Analysis

Material effect

Practical effect of degree day model choice on energy consumption and monetary value calculations

What would be the practical effect on BC Hydro Load Forecasting energy consumption calculations (for residential customers) of the choice of HDD/CDD forecasting model? The model choices were: Static Moving Average, Dynamic Moving Average, or probabilistic model with climate index inputs.

The material effect was revealed by translating changes in degree day units into changes in energy units (GWh) and corresponding changes in monetary values. One way of accomplishing the translation was by using BC Hydro Load Forecasting's Weather Normalization Methodology (explained on the next slide) which was embedded in their ResHist spreadsheet model.

A sensitivity analysis was the clearest way to show how HDD uncertainties would propagate into energy consumption and monetary value uncertainties. Dec and Jul represent the typical annual range of values for monthly HDD.

The next three slides illustrate how the ResHist spreadsheet was used for the sensitivity analyses.

Roland V Wahlgren, Load Research Analyst BC Hydro Customer Information Management—Load Analysis

Material effect

Degree Day to Energy Consumption Translation within Load Forecasting's ResHist Model

Translating degree days into residential energy consumption was accomplished by BC Hydro Load Forecasting using an empirical polynomial. The explanation concluding at the bottom of this slide was by BC Hydro Load Analyst Scott Albrechtsen (personal communication).

Blended Degree Day Measurement

The weather variable used is ... a "blended" Total Degree Day measurement (BTDD). This a weighted 3 month moving average summation of HDDs and CDDs where the lagged month's weather is weighted the heaviest (@50%) and the current and 2 months lagged weather are weighted also (each @25%). [Load Forecasting] uses the square (BTDD2) and cubic (BTDD3) as variables in [their] weather regressions also.

$BTDD_{t} = .5* \left[\sum (HDD_{t-1}, CDD_{t-1}) \right] + .25* \left[\sum HDD_{t}, CDD_{t}, HDD_{t-2}, CDD_{t-2} \right]$

Weather Normalization Methodology

[Load Forecasting] does 36 month-moving monthly weather regressions during [their] monthly weather normalizations. Each month every segment consists of one regression that consists of 36 observations based on the last 3 years of billing data.

Weather Normalization Regression Structure

[Load Forecasting's] weather normalization is essentially a "weather adjustment" where[by] the weather effect is [eliminated] from the actual billed figures.

Actual $_kWh_t = \beta_0 + \beta_1 * BTDD_t + \beta_2 * BTDD_t^2 + \beta_3 * BTDD_t^3 + \varepsilon_t$

This equation was used in the following "material effect analyses" to convert degree days to energy consumption (GWh). A unique vector of coefficients, (β_0 , β_1 , β_2 , β_3) existed for each point-in-time (month-year) calculation related to prevailing characteristics of the grid and aggregate customer demand for (consumption of) electrical power (electrical energy).

Summary of sensitivity analyses

- The sensitivity analyses apply to any HDD forecasting method
- Uncertainties and errors have a much greater effect on energy consumption and monetary value estimates in Dec than in Jul
 - Sensitivity of Energy Consumption to HDD was 3.4 times greater in Dec than in Jul (2008)
 - Sensitivity of Energy Consumption to HDD MAPE was 89 times greater in Dec than in Jul (2008)
 - Sensitivity of Energy Consumption Difference to HDD MAPE was 89 times greater in Dec than in Jul
 - Sensitivity of Energy Consumption Monetary Value Difference to HDD MAPE was 89 times greater in Dec than in Jul (2008)
 - Other months would have lower sensitivities compared to the Dec/Jul relationship
- Examples of the effect of forecasting errors:
 - An error of 11 HDD in Dec 2008 created an annual energy consumption error of 16 GWh worth about \$1 million
 - An error of 11 HDD in Jul 2008 created an annual energy consumption error of 4.7 GWh worth about \$294,000
- Examples of the effect of forecasting improvements:
 - An improvement of Dec 2008 HDD MAPE of 2.1% corresponded to an annual energy consumption difference of 16 GWh worth about \$1 million
 - An improvement of Jul 2008 HDD MAPE of 2.1% corresponded to an annual energy consumption difference of 0.18 GWh worth about \$11,000
- Return of investment in Degree Day forecasting research can be maximized by focusing on improving HDD forecasts for heating season months—the new probabilistic model could improve Dec HDD by 2% to 3% (see table, Slide 107)—annual improvements worth at least \$1 million in monetary value

BChydro

Roland V Wahlgren, Load Research Analyst BC Hydro Customer Information Management—Load Analysis

Compare material effect of degree-day forecasting errors for a period of decreasing monthly HDD and another of stable monthly HDD

Method

•Considered the periods Apr 1993–Mar 1998 (decreasing monthly HDD, Slide 11) and Apr 2001–Mar 2006 (stable monthly HDD, Slide 11)

•Material effects that count for BC Hydro include errors in predicting energy consumption and associated monetary value (16 GWh \approx \$1 million)

•Load Forecasting's ResHist model contained values for the coefficients, (β_0 , β_1 , β_2 , β_3), used in the HDD to energy consumption conversion equation (Slide 118)

Actual $_kWh_t = \beta_0 + \beta_1 * BTDD_t + \beta_2 * BTDD_t^2 + \beta_3 * BTDD_t^3 + \varepsilon_t$

•Because the coefficients were unique to each point-in-time (month-year), substitution of HDD and CDD into the ResHist model (Slides 119–120) was made only at the 60 points-in-time corresponding to Apr 1993–Mar 1998 and Apr 2001–Mar 2006. Only this one change affecting the "Normal Heat Deg Days" and "Normal Cool Deg Days" pair of columns was made to the ResHist model

•Results were collected in a Model Comparison Table (Slide 127) and charts (Slides 128 to 137) were produced

Results

•The charts revealed opportunities for tuning ARIMA performance. In contrast, Moving Average models cannot be tuned •The charts show that the ARIMA model can outperform moving average models during periods of HDD non-stationarity

Decreasing HDD: Static Moving Average Model cannot be tuned to increase accuracy. "What you see is what you get".

Errors in shaded range are not material in

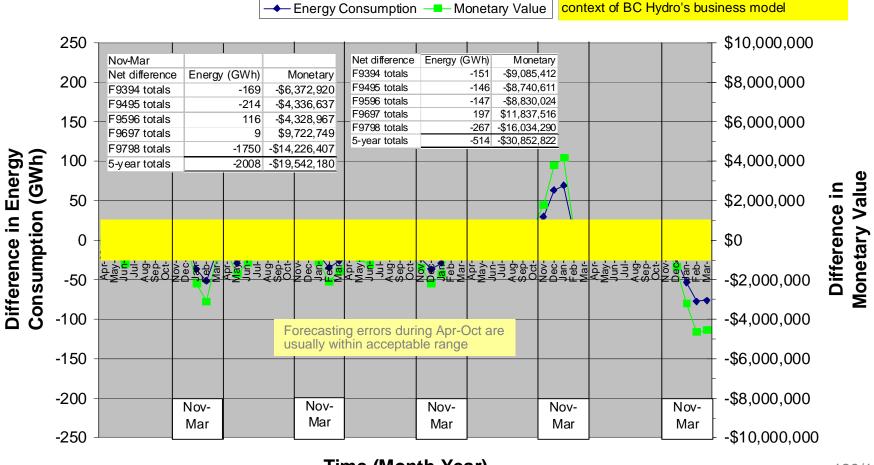

Static Moving Average Forecasting Method: Differences in Total Res. Energy Consumption & Monetary Value during Apr 93 - Mar 98 DD forecast period (Lower Mainland)

Decreasing HDD: Dynamic Moving Average Model cannot be tuned to increase accuracy. "What you see is what you get".

Errors in shaded range are not material in

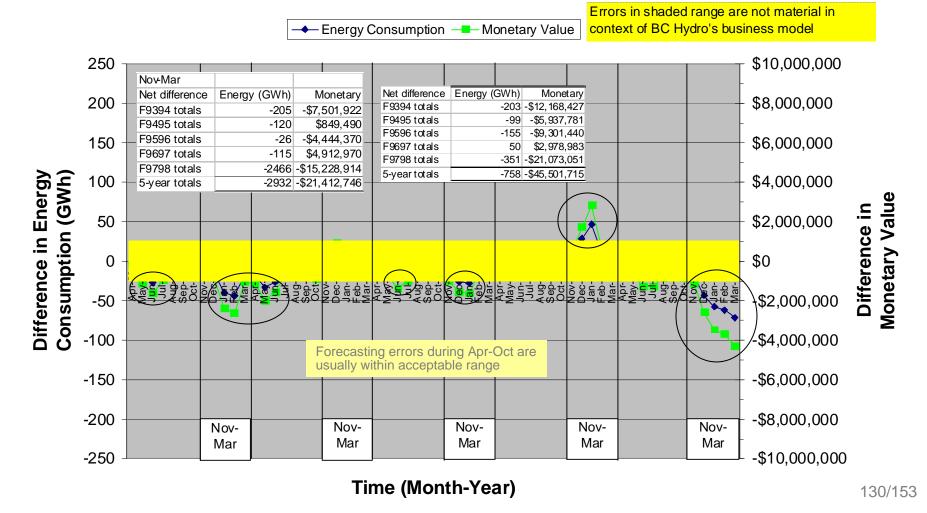

Dynamic Moving Average Forecasting Method: Differences in Total Res. Energy Consumption & Monetary Value during Apr 93 - Mar 98 DD forecast period (Lower Mainland)

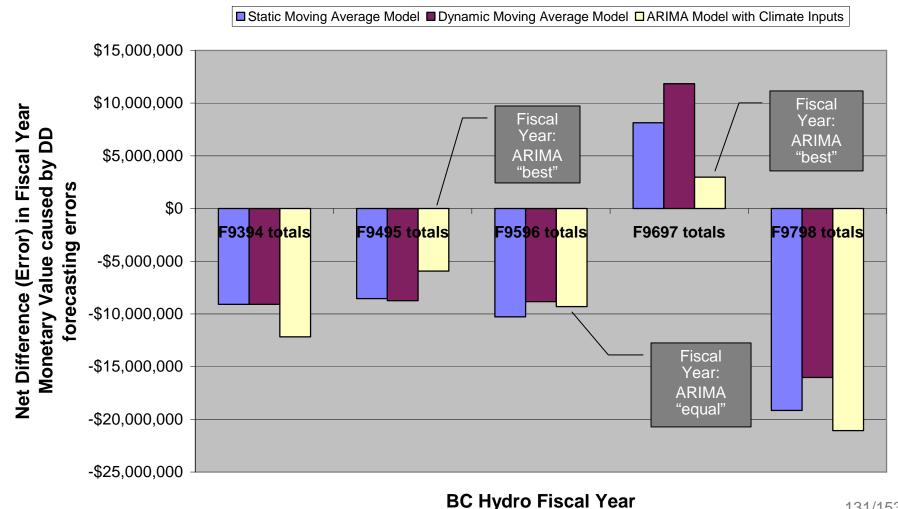

Time (Month-Year)

Decreasing HDD: Opportunities for tuning ARIMA model are circled. Tuning is done by improving understanding of how climate index inputs should be applied.

ARIMA Probabilistic Forecasting Method with Climate Index Inputs: Differences in Total Res. Energy Consumption & Monetary Value during Apr 93 - Mar 98 DD forecast period (Lower Mainland)

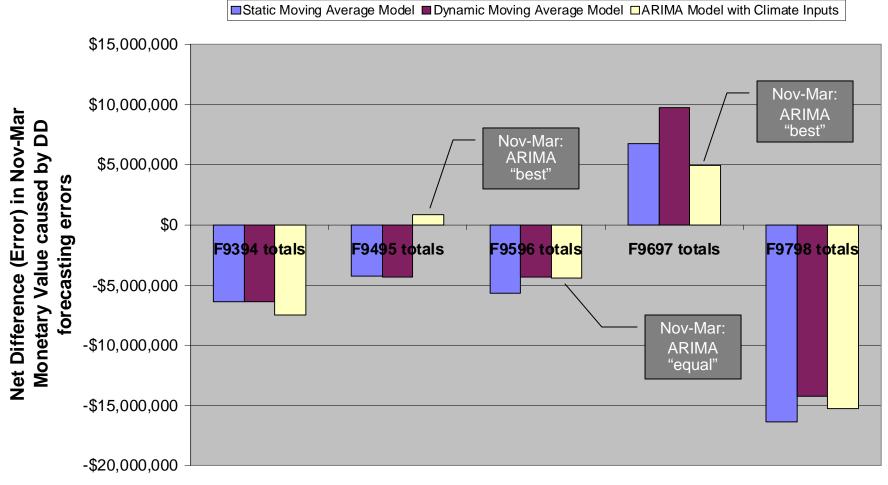

Net Differences in Fiscal Year Monetary Values for Forecast Models caused by DD forecasting differences from actual (1993-1998)

131/153

Decreasing HDD

Net Differences in Nov-Mar Monetary Values for Forecast Models caused by DD forecasting differences from actual (1993-1998)

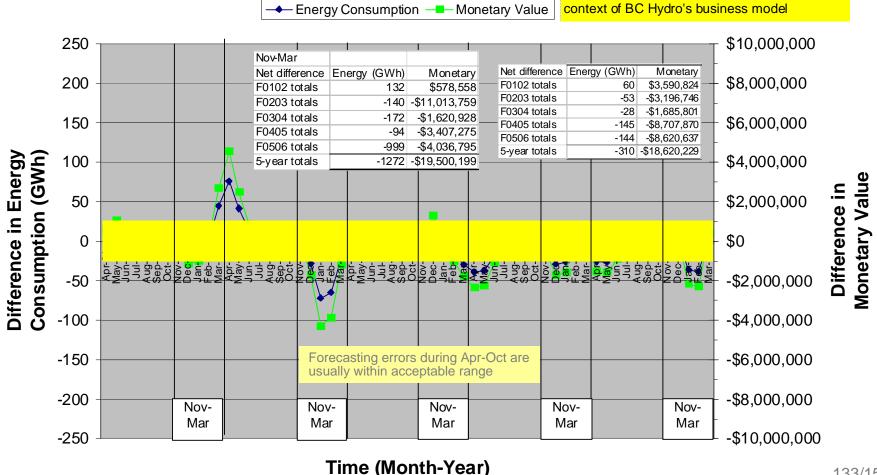

BC Hydro Fiscal Year (Nov–Mar)

Decreasing HDD

Stable HDD: Static Moving Average Model cannot be tuned to increase accuracy. "What you see is what you get".

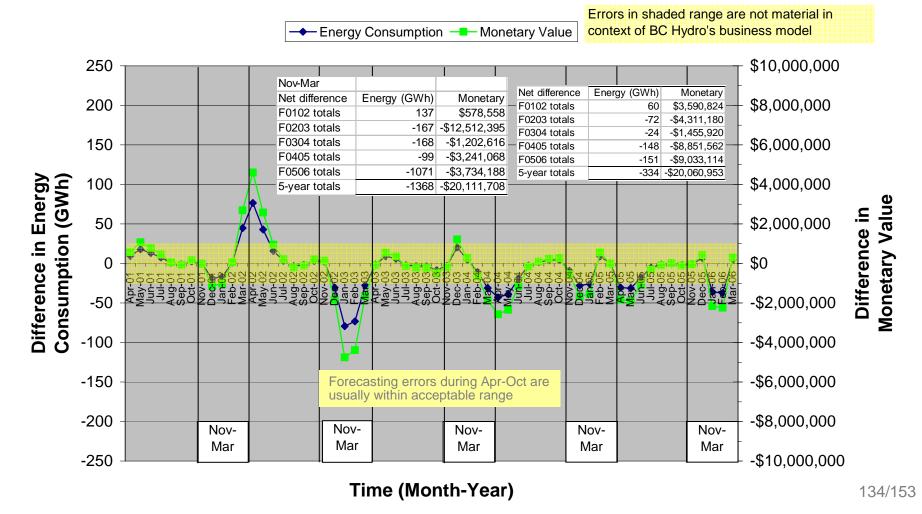

Errors in shaded range are not material in

Static Moving Average Forecasting Method: Differences in Total Res. Energy Consumption & Monetary Value during Apr 01 - Mar 06 DD forecast period (Lower Mainland)

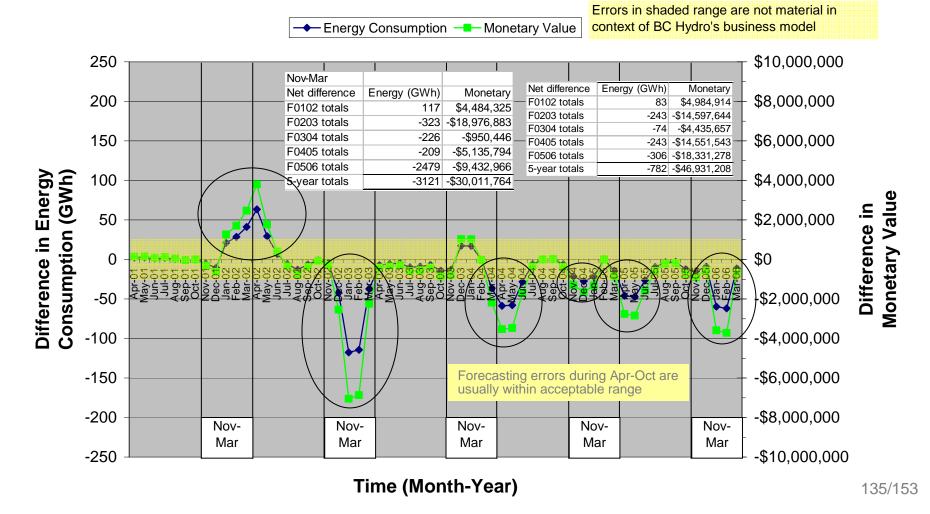

Stable HDD: Dynamic Moving Average Model cannot be tuned to increase accuracy. "What you see is what you get".

Dynamic Moving Average Forecasting Method: Differences in Total Res. Energy Consumption & Monetary Value during Apr 01 - Mar 06 DD forecast period (Lower Mainland)

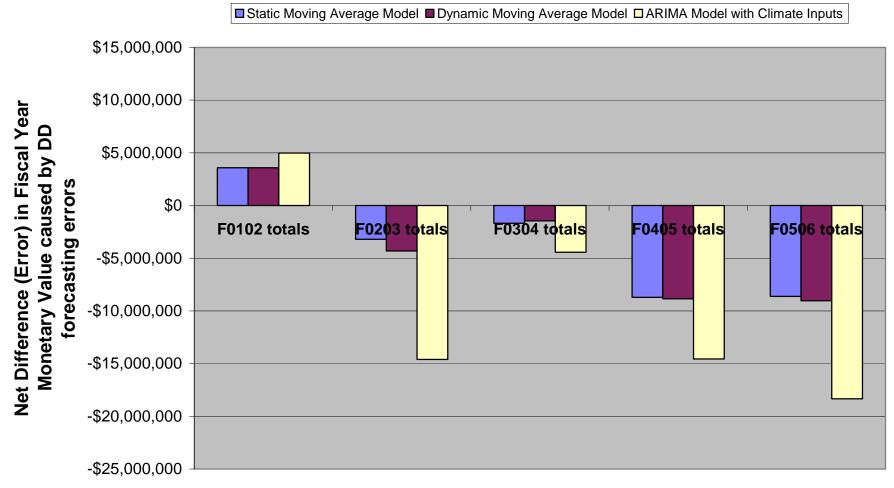

Stable HDD: Opportunities for tuning ARIMA model are circled. Tuning is done by improving understanding of how climate index inputs should be applied.

ARIMA Probabilistic Forecasting Method with Climate Index Inputs: Differences in Total Res. Energy Consumption & Monetary Value during Apr 01 - Mar 06 DD forecast period (Lower Mainland)

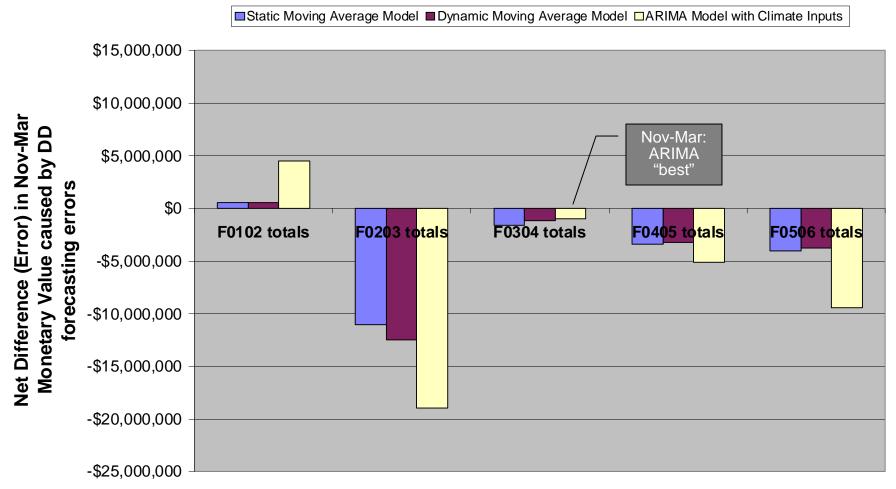

Stable HDD; ARIMA offered no advantage when entire year considered

Net Differences in Fiscal Year Monetary Values for Forecast Models caused by DD forecasting differences from actual (2001-2006)

BC Hydro Fiscal Year

Net Differences in Nov-Mar Monetary Values for Forecast Models caused by DD forecasting differences from actual (2001-2006)

BC Hydro Fiscal Year (Nov–Mar) 137/153

Interactive Spreadsheet

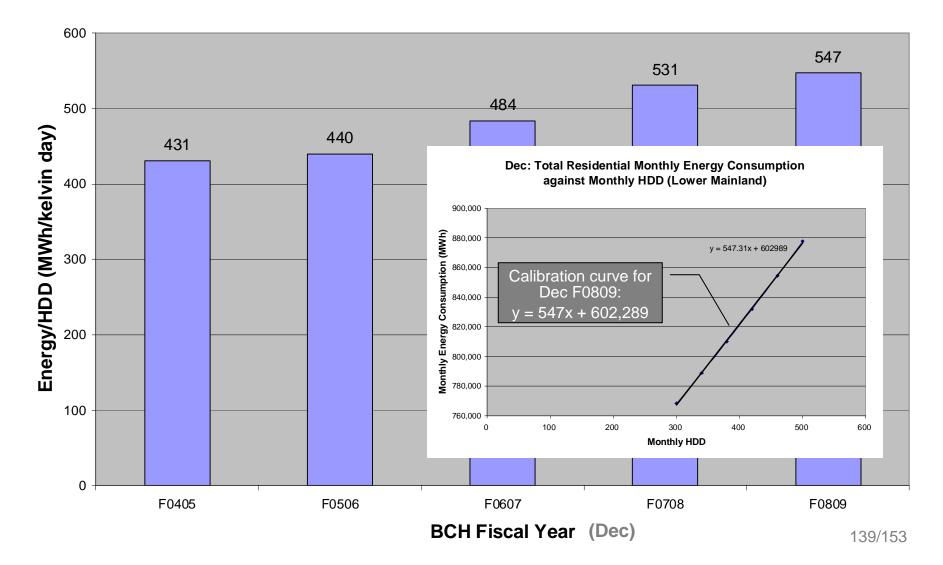

- Screen shots of spreadsheets are in the following slides
- Material effect of errors in HDD was illustrated quantitatively for the Lower Mainland winter (Nov–Mar)
- Designed to accept 5 years of data from any region as an interactive demonstration tool
 - Warning No. 1: Slope of calibration curves changes noticeably from year to year, even over 5 years; see example of month of Dec, Slide 139)
 - Warning No. 2: Calibrations may be affected by various factors, including the fact that consumption of electrical energy per account has been increasing In the Lower Mainland Region during the period Apr 1981 to Mar 2009 (Slide 140)
 - Theoretically, it should have been possible to construct calibration curves ("performance lines" in the nomenclature of Day, 2006) using "total monthly energy consumption for Lower Mainland" (normalized for increasing number of accounts) or "monthly energy consumption per account" against "monthly HDD" but these attempts were unsuccessful. The reason was likely to be that stated above in the second warning. The calibration curves used in the spreadsheet were generated by feeding artificial HDD data into the Load Forecasting ResHist Model for the months Nov–Mar of F0809 (Lower Mainland). Calibration curves are specific to each BC Hydro sales region.
- Test data (actual and predicted HDD) was from the two periods examined earlier in this document
 - Data Apr 1993 to Mar 1998 represented forecast results from a period of decreasing monthly HDD
 - Data Apr 2001 to Mar 2006 represented forecast results from a period of stable monthly HDD
- Result: View monthly, annual, and 5-year cumulative value of errors in terms of:
 - Energy Consumption (GWh)
 - Monetary Value

BC Hydro Fiscal Year

Summary

•Degree day forecasts with ARIMA can be based on meaningful climatological inputs; more information content about physical processes than purely empirical methods

•Forecasts can be quantified with 5% confidence limits

•Quality of ARIMA forecasts was tested by back-casting, correlating actual HDD values with predicted values. Quality varied by month and by region with tested predictions always significant for Vancouver, Victoria, and Prince George (46 year test; 1963–2008). Kamloops ARIMA forecast quality was affected by the short period of observations (5 year test; 2004–2008). In all four regions, ARIMA backcasts had "mean absolute percentage error" (MAPE) always less than the MAPE for the 10-year moving average backcasts

•Six separate "acid tests" assumed forecasts were made in Mar 1993 (decreasing HDD trend) or Mar 2001 (no HDD trend); Forecasts could be compared to actual monthly HDD for the next 60 months; Results were: (1) ARIMA model outperformed (Nov-Mar) moving average models during period with trend; (2) ARIMA model was no better than moving average models during period with no trend (3) ARIMA model climate input decisions changed with duration of time series record

•Material effect (on improved accuracy of energy consumption calculations) of using the ARIMA model sometimes exceeded \$1 million in monetary value

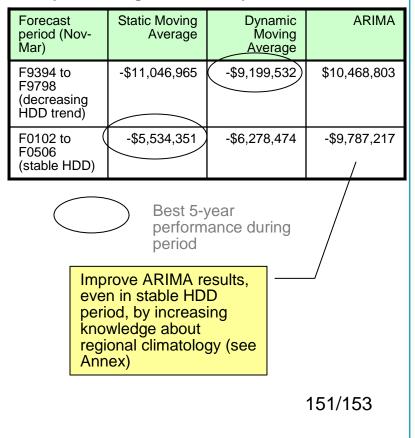

•ARIMA models are used widely in the physical and social sciences; Software such as SAS JMP offers relative ease of use

•Similar results will be obtained by different analysts

•Forecasts can be updated following documented methods

•ARIMA probabilistic model with climate index inputs has lowest risk of unknowingly embarking on a period of over or under-estimating HDDs or CDDs compared to moving average models [such as happened to BC Hydro in the 1980's and 1990's (Mansfield, 1996)]

Five-year (Nov-Mar) total monetary values of errors experienced by forecasting methods when compared using interactive spreadsheet model

Action Plan

Action Plan

- Introduce new Degree Day Forecasting Model to BC Hydro Load Forecasters and Meteorologists
- Train two BC Hydro employees (e.g., Load Research Analysts or Load Forecasters) to use the model
- Implement model for Degree Day Forecasting
 - Monitor performance month by month so that feedback from MAPE results helps develop expertise with appropriate use of climate index inputs
 - Monitor the climatology literature for new climate indices, applicable to the regional climate of BC, that may make the new model more powerful
 - Budget time and resources for regular experimentation with model to improve accuracy. According
 to Mansfield (1996; pages 4–6), HDD forecasting inaccuracies can result in large errors estimating
 electricity consumption and revenue. The sensitivity analyses and experiments with material effect
 confirmed Mansfield's statement. Diligent, scheduled experimentation with the proposed new
 forecasting model is likely to result in worthwhile improvements in HDD and CDD forecasting
 accuracy

Annex

Annex 1 (1 of 2) — Experiments with various climate input combinations to reduce forecasting errors

- Test effect on forecasting accuracy of changing ARIMA climate inputs:
- Focus on Apr 01 to Mar 06 forecast errors
- Errors > \$1 million revealed on Slide 135 (copy shown here; errors with material effect were circled)
- Forecast for Jan used climate indices PNAI and GMMTA
- Jan forecasts errors resulted in errors exceeding \$1 million, each forecast year
- Revised forecast #1 used climate indices NPI, ALPI, and RNAI (based on chart, slide 109 showing ANOVA Prob > F was 0.0001 for these 3 indices)
- Revised forecast #2 used climate indices PNAI and LODI; rule #1 [ANOVA Prob > F] < 0.05; rule #2 correlation coefficient relating indices , r < 0.5
- Results of revised forecasts are tabulated on the next slide
- Discovering proper combination of climate indices to use for a month is crucial for accurate forecasting with ARIMA method
- Once best combination for a month is found, use it for all new forecasts involving that month
- This method recognizes regional climate processes
- Improved understanding of BC's climate in each BCH sales region can improve forecasting accuracy refer to slide 152 "Action Plan"
